 Fix a morphism of discrete commutative rings 
\[ \phi : R \to S \]
Fix a morphism of discrete commutative rings $\phi : R \rightarrow S$

Descent theory answers the question: What information do we need to study $R$-modules using $S$-modules?
Fix a morphism of discrete commutative rings \( \phi : R \to S \).

Descent theory answers the question: What information do we need to study \( R \)-modules using \( S \)-modules?

The answer is: descent data. Descent data lets us “descend” information about \( S \)-modules to information about \( R \)-modules.
Fix a morphism of discrete commutative rings \( \phi : R \to S \).

Descent theory answers the question: What information do we need to study \( R \)-modules using \( S \)-modules?

The answer is: descent data. Descent data lets us “descend” information about \( S \)-modules to information about \( R \)-modules.

If we apply \( \text{Spec}(\mathcal{-}) \) to our rings and think of our modules as sheaves, then descent data manifests as “gluing data.”
Definition

A descent datum for a morphism of commutative rings $\phi : R \to S$ consists of:

- an $S$-module $M$
- an isomorphism (of $S \otimes_R S$-modules), $\theta : p_0^*(M) \xrightarrow{\cong} p_1^*(M)$
- a commutative diagram which constitutes the cocycle condition:

$$
p_{10}^*(M) \cong p_{02}^*(M)
\quad p_0^*(\theta)
\quad p_2^*(\theta)
\quad p_{00}^*(M) \cong p_{01}^*(M) \xrightarrow{p_1^*(\theta)} p_{11}^*(M) \cong p_{12}^*(M)
$$
There is a category of descent data. It is the limit of the diagram:

\[
\begin{array}{ccc}
S\text{Mod} & \longrightarrow & (S \otimes_R S)\text{Mod} \\
& \longrightarrow & (S \otimes_R S \otimes_R S)\text{Mod}
\end{array}
\]
This diagram is just $(-)Mod$ applied to the first three levels of the *Amitsur complex* $S/R^\bullet$.

\[
\begin{array}{c}
\vdots \\
S \otimes_R S \otimes_R S \\
\uparrow \\
S \otimes_R S \\
\uparrow \\
S \\
\uparrow \\
R
\end{array}
\quad \sim \quad
\begin{array}{c}
\vdots \\
(S \otimes_R S \otimes_R S) Mod \\
\uparrow \\
(S \otimes_R S) Mod \\
\uparrow \\
S Mod \\
\uparrow \\
R Mod
\end{array}
\]
When does the category of descent data tell us about the category of \( R \)-modules?

**Definition**

A morphism of rings \( R \to S \) is said to be a *descent* morphism if the functor \( RMod \to \lim \text{Mod}(S/R^\bullet) \) is fully faithful.
When does the category of descent data tell us about the category of $R$-modules?

**Definition**
A morphism of rings $R \to S$ is said to be a *descent* morphism if the functor $RMod \to \lim Mod(S/R^\bullet)$ is fully faithful.

**Definition**
A morphism of rings $R \to S$ is said to be an *effective descent* morphism if the functor $RMod \to \lim Mod(S/R^\bullet)$ is an equivalence.
When does the category of descent data tell us about the category of $R$-modules?

**Definition**
A morphism of rings $R \to S$ is said to be a *descent* morphism if the functor $RMod \to \lim \text{Mod}(S/R^\bullet)$ is fully faithful.

**Definition**
A morphism of rings $R \to S$ is said to be an *effective* descent morphism if the functor $RMod \to \lim \text{Mod}(S/R^\bullet)$ is an equivalence.

**Example**
Grothendieck showed that faithfully flat morphisms of commutative rings are of effective descent.
We’d like to classify all possible descent data on an $S$-module $M \cong N \otimes_R S$ for an $R$-module $N$. 
We’d like to classify all possible descent data on an $S$-module $M \cong N \otimes_R S$ for an $R$-module $N$.

Definition

Let $\phi : R \to S$ be an effective descent morphism, and $N$ an $R$-module. Then a twisted form for $N$ along $\phi$ is an $R$-module $N'$ such that $N' \otimes_R S \cong N \otimes_R S$.

There is a set of twisted forms, denote it $\text{Tw}_\phi(N)$. 
We’d like to classify all possible descent data on an $S$-module $M \cong N \otimes_R S$ for an $R$-module $N$.

**Definition**

Let $\phi : R \to S$ be an effective descent morphism, and $N$ an $R$-module. Then a twisted form for $N$ along $\phi$ is an $R$-module $N'$ such that $N' \otimes_R S \cong N \otimes_R S$.

There is a set of twisted forms, denote it $Tw_\phi(N)$.

**Theorem (See e.g. Waterhouse)**

If $\phi$ is an effective descent morphism then:

$$Tw_\phi(N) \cong Desc_\phi(N \otimes_R S)$$
We can compute descent data and twisted forms using cohomology.
We can compute descent data and twisted forms using cohomology.

**Definition**

*For an R-module N, define $\text{Aut}(N) : CRng^R \to \text{Group}$ by $\text{Aut}(N)(S) = \text{Aut}_S(S \otimes_R N)$.*
We can compute descent data and twisted forms using cohomology.

**Definition**

For an $R$-module $N$, define $\text{Aut}(N) : CRng \backslash R \to \text{Group}$ by $\text{Aut}(N)(S) = \text{Aut}_S(S \otimes_R N)$.

**Theorem (Ibid.)**

The set of twisted forms for $N$ along $\phi : R \to S$ is in bijection with the first (non-abelian) cohomology of the cosimplical group $\text{Aut}(N)(R/S^\bullet)$:

\[ \text{Aut}(N)(S) \xrightarrow{\text{Aut}(N)(S \otimes_R S)} \text{Aut}(N)(S \otimes_R S \otimes_R S) \cdot \cdot \cdot \]
We can compute descent data and twisted forms using cohomology.

**Definition**

*For an $R$-module $N$, define $Aut(N) : CRng \rightarrow \text{Group}$ by $Aut(N)(S) = Aut_S(S \otimes_R N)$.*

**Theorem (Ibid.)**

*The set of twisted forms for $N$ along $\phi : R \rightarrow S$ is in bijection with the first (non-abelian) cohomology of the cosimplical group $Aut(N)(R/S^{\bullet})$:*

$$Aut(N)(S) \rightarrow Aut(N)(S \otimes_R S) \rightarrow Aut(N)(S \otimes_R S \otimes_R S) \cdots$$

We often call the above cohomology group the *descent cohomology* of $N$. 
Sketch Proof:

- The module \( p_0^*(N) = (N \otimes_R S) \otimes_S (S \otimes_R S) \cong N \otimes_R S \otimes_R S \)
supports a canonical descent datum given by twisting the \( S \) factors:

\[
\text{can} : p_0^*(N \otimes_R S) \xrightarrow{\cong} p_1^*(N \otimes_R S).
\]

- Any other descent datum \( \phi \) gives an automorphism after inverting \( \text{can} \):

\[
\text{can}^{-1} \circ \phi : p_0^*(N \otimes_R S) \xrightarrow{\cong} p_0^*(N \otimes_R S).
\]

- A suitable automorphism can be composed with the canonical descent datum to obtain a new descent datum.
To homotopy theory...

Definition (Lurie)

For \( \phi : R \to S \), a map of \( \mathbb{E}_\infty \)-ring spectra, the \( \infty \)-category of descent data for \( \phi \) is the totalization of the cosimplicial \( \infty \)-category (again based on the Amitsur complex):

\[
S\text{Mod} \xrightarrow{\longrightarrow} (S \otimes_R S)\text{Mod} \xrightarrow{\longrightarrow} (S \otimes_R S \otimes_R S)\text{Mod} \xrightarrow{\longrightarrow} \cdots
\]
To homotopy theory...

Definition (Lurie)

For $\phi : R \to S$, a map of $\mathbb{E}_\infty$-ring spectra, the $\infty$-category of descent data for $\phi$ is the totalization of the cosimplicial $\infty$-category (again based on the Amitsur complex):

$$\text{SMod} \xrightarrow{\sim} (S \otimes_R S) \text{Mod} \xrightarrow{\sim} (S \otimes_R S \otimes_R S) \text{Mod} \xrightarrow{\sim} \cdots$$

Homotopical descent data can be given as an invertible 1-cell and a sequence of higher homotopy cocycle conditions:
Definition

Under the assumptions given above, a descent datum for $\phi : R \to S$ is:

- an $S$-module $M$,
- an invertible 1-cell $\theta : p_0^*(M) \to p_1^*(M)$,
- a 2-cell

$$p_{10}^*(M) \simeq p_{02}^*(M)$$

$$
\begin{array}{c}
p_0^*(\theta) \\
p_{00}^*(M) \simeq p_{01}^*(M) \\
p_1^*(\theta) \\
p_{11}^*(M) \simeq p_{12}^*(M)
\end{array}
$$

- higher $n$-cells satisfying higher cocycle conditions...
Definition

For a morphism of $\mathbb{E}_\infty$-ring spectra $\phi : R \to S$, and an $R$-module $N$, the space of twisted forms of $N$ is the homotopy limit of the cospan

$$R\text{-Mod} \xrightarrow{-\otimes_R S} \text{Desc}_\phi \xleftarrow{N\otimes_R S} \ast.$$
**Definition**

For a morphism of $E_\infty$-ring spectra $\phi : R \to S$, and an $R$-module $N$, the space of twisted forms of $N$ is the homotopy limit of the cospan

$$
\begin{align*}
\text{RMod} & \xrightarrow{-\otimes_R S} \text{Desc}_\phi \\
& \xleftarrow{N \otimes_R S} *.
\end{align*}
$$

**Example**

Along the morphism $S \to MU$, $\Sigma_+ BU$ is a twisted form of $MU$, as evidenced by the Thom isomorphism

$$MU \wedge \Sigma_+ BU \simeq MU \wedge MU.$$
Remark

- This generalizes the descent 2-category for 2-categorical descent as studied by Ross Street, Claudio Hermida, Lawrence Breen, and others.
Remark

- This generalizes the descent 2-category for 2-categorical descent as studied by Ross Street, Claudio Hermida, Lawrence Breen, and others.

- Kathryn Hess describes descent data as a category of comodules over a comonad. Her theory, if translated into the language of $\infty$-categories, is equivalent to this one.
Theorem (Riehl, Verity)

For a homotopy coherent monad of quasicategories $T : C \to C$, the quasicategory of descent data is the homotopy limit of the cosimplicial diagram of quasicategories:

$$
\begin{array}{c}
TC & \longrightarrow & TTC & \longrightarrow & TTTT & \longrightarrow & \cdots \\
\end{array}
$$
Theorem (Riehl, Verity)

For a homotopy coherent monad of quasicategories $T : C \to C$, the quasicategory of descent data is the homotopy limit of the cosimplicial diagram of quasicategories:

$$TC \to TTC \to TTTT \to \cdots$$

Remark

For us, the homotopy coherent monad of interest is the extension-of-scalars monad associated to $\phi : R \to S$. 
Theorem (B.)

Let $\phi : R \to S$ be a morphism of $\mathbb{E}_\infty$-ring spectra which is of effective descent. Then for an $R$-module $N$, there is an equivalence of $\infty$-categories:

$$T_{\phi}(N) \simeq \text{Desc}_\phi(N \otimes_R S).$$
Proof.

Compare these two homotopy pullback diagrams of quasicategories. Since $\phi$ is of effective descent, $R\text{Mod} \cong \text{Desc}_\phi$ so the pullbacks are equivalent.

\[
\begin{align*}
TW_\phi(N) & \longrightarrow * \\
\downarrow & \\
R\text{Mod} & \longrightarrow S\text{Mod} \\
\downarrow & \\
\text{Desc}_\phi(N \otimes_R S) & \longrightarrow * \\
\downarrow & \\
\text{Desc}_\phi & \longrightarrow S\text{Mod}
\end{align*}
\]
Similarly to the discrete case, we now want to determine the space of twisted forms using some kind of “cohomology.”

However, since there is a space of twisted forms, we need a Bousfield-Kan spectral sequence to get at this information!

For a given $R$-module $N$, the cosimplicial space of interest is:

$$ Aut(N)(S) \xrightarrow{\sim} Aut(N)(S \otimes_R S) \xrightarrow{\sim} Aut(N)(S \otimes_R S \otimes R S) $$

Specifically we want to understand the data in cohomological degree one (i.e. the homotopical analogue of $H^1$).
Theorem (B.)

For a morphism of $\mathbb{E}_\infty$-ring spectra $\phi : R \to S$ and $N$ an $R$-module, the set of isomorphism classes of descent data on $N \otimes_R S$ is equivalent to $\pi_0 \text{Tot}(BAut(R/S^\bullet))$.

Remark

The Bousfield-Kan spectral sequence converges to the homotopy of the above totalization:

$$\pi^s \pi_t \Rightarrow \pi_{t-s} \text{Tot}(BAut(R/S^\bullet))$$

If our spaces are sets (e.g. 0-truncated) then $\pi_{-1}$ of the totalization recovers the first nonabelian cohomology $H^1(R/S^\bullet; Aut(N))$. 
Sketch of proof:

- $\text{Aut}(\cdot)$ corresponds to taking based loops of $R/S^\bullet$ with base point the canonical descent datum on $N \otimes_R S$ (compare with Dwyer-Kan classification spaces).
- This forgets all other components and produces a cosimplicial loop space, which admits a delooping by a cosimplicial space.
- $\pi_0$ of this delooping is precisely the set of descent data on $N \otimes_R S$. 

$\square$
Remark

- If $\phi : R \to S$ is a Galois (or Hopf-Galois) extension in the sense of Rognes, the above construction can be reinterpreted as homotopical Galois cohomology.
- In that case, a descent datum corresponds to an (co)action of a (Hopf-)Galois (algebra) group.
- The spectral sequence is a homotopy (co)fixed points spectral sequence.
- Tyler Lawson and David Gepner are doing computations along these lines for the Galois extensions $KO \to KU$.
- Vesna Stojanoska and Akhil Mathew are also doing these kinds of computations for $TMF \to TMF(n)$.
Thom Spectra

We can get Thom spectra (e.g. $MU$, $M\Xi$, $X(n)$, $MSp$ etc.) by taking global sections of bundles defined by functions $f : X \to BGL_1(S)$ for $X$ some space.
Thom Spectra

- We can get Thom spectra (e.g. $MU$, $M\Xi$, $X(n)$, $MSp$ etc.) by taking global sections of bundles defined by functions $f : X \to BGL_1(S)$ for $X$ some space.

- We can then ask about other bundles which are locally equivalent along the “cover” $S \to Mf$. 

We can get Thom spectra (e.g. $MU$, $M\Xi$, $X(n)$, $MSp$ etc.) by taking global sections of bundles defined by functions $f : X \to BGL_1(S)$ for $X$ some space.

We can then ask about other bundles which are locally equivalent along the “cover” $S \to Mf$. 

Thom Spectra

- We can get Thom spectra (e.g. $MU$, $MΞ$, $X(n)$, $MSp$ etc.) by taking global sections of bundles defined by functions $f : X \to BGL_1(S)$ for $X$ some space.
- We can then ask about other bundles which are locally equivalent along the “cover” $S \to Mf$.
- For example: the trivial bundle $S[X_+]$ is locally equivalent to $Mf$, and we call this local equivalence the Thom isomorphism

$$Mf \wedge S[X_+] \simeq Mf \wedge Mf.$$  

- Our machinery can compute other twists of such Thom spectra (work in progress).
\( \mathbb{G}_n \)-actions

- For the (profinite-)Galois extension \( L_{K(n)}S \rightarrow L_{K(n)}E_n \) a descent datum corresponds to an \( L_{K(n)} \)-module \( M \) and an action of the Morava stabilizer group \( \mathbb{G}_n \) on \( M \).
$G_n$-actions

- For the (profinite-)Galois extension $L_{K(n)} S \to L_{K(n)} E_n$ a descent datum corresponds to an $L_{K(n)}$-module $M$ and an action of the Morava stabilizer group $G_n$ on $M$.
- The BKSS above would compute actions of $G_n$ on $M$. Are there exotic actions?
$\mathbb{G}_n$-actions

- For the (profinite-)Galois extension $L_{K(n)} \mathbb{S} \to L_{K(n)} E_n$ a descent datum corresponds to an $L_{K(n)}$-module $M$ and an action of the Morava stabilizer group $\mathbb{G}_n$ on $M$.
- The BKSS above would compute actions of $\mathbb{G}_n$ on $M$. Are there exotic actions?
- Compare with Goerss and Hopkins’ identification of the moduli space of spectra $X$ such that $X \wedge E_n \simeq E_n \wedge E_n$ as $B\text{Aut}(\mathbb{G}_n)$ (note, this means it’s connected!).

\hspace{\fill}
\( \mathbb{G}_n \text{-actions} \)

- For the (profinite-)Galois extension \( L_{K(n)}S \rightarrow L_{K(n)}E_n \) a descent datum corresponds to an \( L_{K(n)} \)-module \( M \) and an action of the Morava stabilizer group \( \mathbb{G}_n \) on \( M \).
- The BKSS above would compute actions of \( \mathbb{G}_n \) on \( M \). Are there exotic actions?
- Compare with Goerss and Hopkins’ identification of the moduli space of spectra \( X \) such that \( X \wedge E_n \approx E_n \wedge E_n \) as \( B\text{Aut}(\mathbb{G}_n) \) (note, this means it’s connected!).
- Fully developing this case requires dealing with pro-spectra, see work of Daniel Davis, Gereon Quick, Ethan Devinatz and others for some work in this direction.
Thanks to Andrew Salch, Jack Morava, Kathryn Hess and Tyler Lawson for countless helpful discussions regarding this material.
