

# Unsupervised learning of observation functions in state-space models by nonparametric moment methods

Qingci An  
(Joint work with Fei Lu)

# Outline

- 1 Problem setting
- 2 Generalized moments method
- 3 Loss functionals
- 4 Identifiability by quadratic loss functional
- 5 Numerical Examples

# Unsupervised learning

**Data:** Unlabeled input  $X$ , output  $Y$ .

**Goal:** Learn the function  $f$  that  $Y = f(X)$ .

# Unsupervised learning

**Data:** Unlabeled input  $X$ , output  $Y$ .

**Goal:** Learn the function  $f$  that  $Y = f(X)$ .

## Problem formulation

Consider the state-space model:

$$\begin{array}{ll} \text{State model:} & dX_t = a(X_t)dt + b(X_t)dB_t, \quad \text{with } a, b \text{ known;} \\ \text{Observation model:} & Y_t = f_{true}(X_t), \quad \text{with } f_{true} \text{ unknown.} \end{array}$$

**Data:**  $\{Y_{t_0:t_L}^{(m)}\}_{m=1}^M$ .

**Goal:** Identify the observation function  $f_{true}$ .

# Generalized moments method

Let  $g : \mathbb{R}^{L+1} \rightarrow \mathbb{R}^K$  is a functional of the trajectory  $Y_{t_0:t_L}$ . We are matching the moments

$$\begin{aligned}\mathbb{E}[g(Y_{t_0:t_L})] &\longleftrightarrow \mathbb{E}[g(f(X_{t_0:t_L}))]. \\ &\approx \frac{1}{M} \sum_{m=1}^M g(Y_{t_0:t_L}^{(m)}) \\ &=: E_M[g(Y_{t_0:t_L})]\end{aligned}$$

We estimate the observation function  $f_{true}$  by minimizing a notion of discrepancy between these two empirical generalized moments:

$$\hat{f} = \arg \min_{f \in \mathcal{H}} \mathcal{E}_M(f),$$

where  $\mathcal{E}_M(f) := \text{dist}(E_M[g(Y_{t_0:t_L})], \mathbb{E}[g(f(X_{t_0:t_L}))])^2$

# Proper choice of $g$

For efficient optimization, we select the functional  $g$  such that the moments  $\mathbb{E}[g(f(X_{t_0:t_L}))]$  for  $f = \sum_{i=1}^n c_i \phi_i$  can be efficiently evaluated for all  $c = (c_1, \dots, c_n)$ .

For example,

- 1  $g_1(Y_{t_0:t_L}) = Y_{t_0:t_L}$ ;
- 2  $g_2(Y_{t_0:t_L}) = Y_{t_0:t_L}^2$ ;
- 3  $g_3(Y_{t_0:t_L}) = (Y_{t_0} Y_{t_1}, \dots, Y_{t_{L-1}} Y_{t_L})$ ;

# Moments from Itô formula

For  $f \in C_b^2$ , i.e., 2nd-order differentiable with bounded derivatives, applying Itô formula:

$$df(X_t) = \nabla f \cdot b(X_t)dW_t + [\nabla f \cdot a + \frac{1}{2}\text{Hess}(f) : b^\top b](X_t)dt.$$

In integral form, it is

$$f(X_{t+\delta}) - f(X_t) = \int_t^{t+\delta} \nabla f \cdot b(X_s)dW_s + \int_t^{t+\delta} \mathcal{L}f(X_s)ds.$$

where the 2nd-order differential operator  $\mathcal{L}$  is

$$\mathcal{L}f = \nabla f \cdot a + \frac{1}{2}\text{Hess}(f) : b^\top b$$

# Moments from Itô formula

For  $Y_t = f_{true}(X_t)$  and  $\Delta Y_t = Y_{t+\delta} - Y_t$ , we have the following equalities for moments

$$\mathbb{E}[\Delta Y_t] = \mathbb{E}\left[\int_t^{t+\delta} \mathcal{L}f_{true}(X_s) ds\right] = \mathbb{E}[\mathcal{L}f_{true}(X_t)\delta] + O(\delta^2),$$

$$\mathbb{E}[Y_t \Delta Y_t] = \mathbb{E}\left[f_{true}(X_t) \int_t^{t+\delta} \mathcal{L}f_{true}(X_s) ds\right] = \mathbb{E}[f \mathcal{L}f_{true}(X_t)\delta] + O(\delta^2),$$

$$\begin{aligned}\mathbb{E}[(\Delta Y_t)^2] &= \mathbb{E}\left[\int_t^{t+\delta} |\nabla f_{true} b(X_s)|^2 ds\right] + \mathbb{E}\left[\left(\int_t^{t+\delta} \mathcal{L}f(X_s) ds\right)^2\right] \\ &\quad + \mathbb{E}\left[\int_t^{t+\delta} \mathcal{L}f(X_s) ds \int_t^{t+\delta} \nabla f b(X_s) dW_s\right] \\ &= \mathbb{E}[|\nabla f_{true} b(X_s)|^2 \delta] + O(\delta^{1.5})\end{aligned}$$

- 1  $g_4(Y_{t_0:t_L}) = (Y_{t_1} - Y_{t_0}, \dots, Y_{t_L} - Y_{t_{L-1}});$
- 2  $g_5(Y_{t_0:t_L}) = (Y_{t_1}(Y_{t_1} - Y_{t_0}), \dots, Y_{t_L}(Y_{t_L} - Y_{t_{L-1}}));$
- 3  $g_6(Y_{t_0:t_L}) = ((Y_{t_1} - Y_{t_0})^2, \dots, (Y_{t_L} - Y_{t_{L-1}})^2);$

# Loss functionals

The generalized moments we consider include the first and the second moments, as well as the one-step temporal correlation:

$$\begin{aligned} \mathcal{E}(f) := & \lambda_1 \underbrace{\frac{1}{L} \sum_{l=1}^L |\mathbb{E}[f(X_{t_l})] - \mathbb{E}[Y_{t_l}]|^2}_{\mathcal{E}_1(f)} + \lambda_2 \underbrace{\frac{1}{L} \sum_{l=1}^L |\mathbb{E}[f(X_{t_l})^2] - \mathbb{E}[Y_{t_l}^2]|^2}_{\mathcal{E}_2(f)} \\ & + \lambda_3 \underbrace{\frac{1}{L} \sum_{l=1}^L |\mathbb{E}[f(X_{t_l})f(X_{t_{l-1}})] - \mathbb{E}[Y_{t_l}Y_{t_{l-1}}]|^2}_{\mathcal{E}_3(f)}, \end{aligned}$$

$\mathcal{E}^M(f) :=$  Replace  $\mathbb{E}[Y_{t_l}]$ ,  $\mathbb{E}[Y_{t_l}^2]$ ,  $\mathbb{E}[Y_{t_l}Y_{t_{l-1}}]$  by their empirical mean.

# Hypothesis space

$$\mathcal{H} = \left\{ f = \sum_{i=1}^n c_i \phi_i : y_{\min} \leq f(x) \leq y_{\max} \text{ for all } x \in \text{supp}(\overline{\rho}_T) \right\}.$$

While ideally  $y_{\min}$  and  $y_{\max}$  are bounds for  $f_{\text{true}}$ , these are typically unknown, and we use instead the empirical upper and lower bounds:

$$y_{\min} = \min\{Y_{t_l}^{(m)}\}_{l,m=1}^{L,M}, \quad y_{\max} = \max\{Y_{t_l}^{(m)}\}_{l,m=1}^{L,M}.$$

The estimator from data is

$$\hat{f}_{\mathcal{H},M} = \sum_{i=1}^n \hat{c}_i \phi_i,$$
$$\hat{c} = \underset{c \in \mathbb{R}^n \text{ s.t. } \sum_{i=1}^n c_i \phi_i \in \mathcal{H}}{\text{arg min}} \mathcal{E}^M(c).$$

# Identifiability by quadratic loss functional

## Definition (Identifiability)

We say that the observation function  $f_{true}$  is *identifiable* by a data-based loss functional  $\mathcal{E}$  on a hypothesis space  $\mathcal{H}$  if  $f_{true}$  is the unique minimizer of  $\mathcal{E}$  in  $\mathcal{H}$ .

Rewrite the quadratic loss function as:

$$\mathcal{E}_1(f) = \langle f - f_{true}, L_{K_1}(f - f_{true}) \rangle_{L^2(\bar{\rho}_T^L)},$$

where

- $L_{K_1}$  is an integral operator with kernel  $K_1$ ,
- $K_1(x, x') = \frac{1}{\bar{\rho}_T^L(x)\bar{\rho}_T^L(x')} \frac{1}{L} \sum_{l=1}^L p_{t_l}(x)p_{t_l}(x')$ ,
- $p_{t_l}$  is the density of  $X_{t_l}$ ,
- $\bar{\rho}_T^L$  is the average density of  $p_{t_l}$ ,  $l = 0, \dots, L$ .

$$\begin{aligned}\nabla \mathcal{E}_1(f) &= L_{K_1}(f - f_{true}) \\ f &= "L_{K_1}^{-1}" L_{K_1}(f_{true})\end{aligned}$$

- 1 When  $L_{K_1}$  is not strictly positive (eg,  $X_t$  stationary process), the inverse problem is *ill-defined* on  $L^2(\bar{\rho}_T^L)$ .
- 2 On the reproducing kernel hilbert space  $\mathcal{H}_{K_1}$ , the operator  $L_{K_1}$  is invertible but **unbounded**, the inverse problem is *ill-posed* on the RKHS.

# Numerical examples: double-well potential

$$dX_t = (X_t - X_t^3)dt + dB_t$$

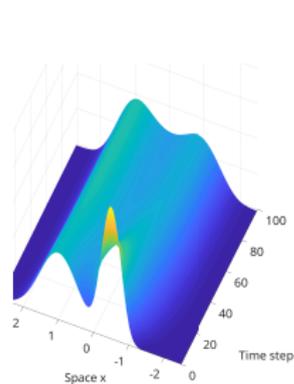

Three observation function  $f(x)$  representing typical challenges:  
nearly invertible, non-invertible, non-invertible discontinuous:

Sine function:  $f_1(x) = \sin(x)$ ;

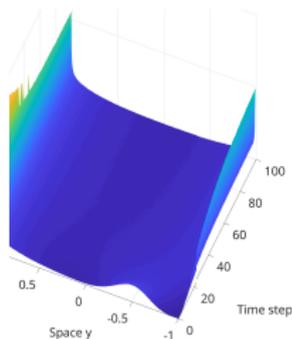

Sine-Cosine function:  $f_2(x) = 2\sin(x) + \cos(6x)$ ;

Arch function:  $f_3(x) = (-2(1-x)^3 + 1.5(1-x) + 0.5) \mathbf{1}_{x \in [0,1]}$ .

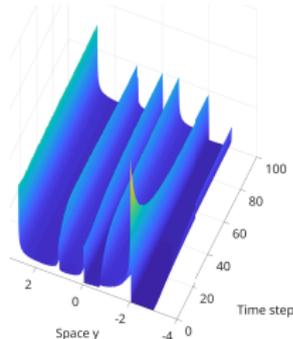

# Numerical examples: double-well potential
